

Installing DevoTeam Dashboard

Sep 18, 2026 · @Youssef

Overview

DevoTeam Dashboard is a conversational sales dashboard: type a question in plain French, get a dashboard back, powered by a local AI model (no API key, no subscription) reading live data from a Google Sheet.

This guide installs it via **Docker** — the recommended method, because a single script handles nearly everything: Docker itself, the local AI model, and the app are all installed and started automatically. You only type two values; nothing else needs to be figured out.

Time needed: 15–30 minutes, mostly unattended downloading. **What's needed beforehand:** nothing to obtain — no API key, no account, no credentials of any kind. Only the Sheet's link and the name of its tab, both visible in the Sheet itself.

Before you start

Nothing needs to be gathered in advance. Docker, the local AI model and the app all install themselves during setup. There is no API key, no service account and no JSON file to manage: the Sheet is read through its public export link, so the only requirement is that the Sheet be shared.

Share the Google Sheet

Open the Sheet → **Share** → under "General access", change it to "**Anyone with the link**", role **Viewer**.

This is safe: the app only ever reads. It cannot write to the Sheet, edit anything, or reach any other Google data — it only reads the rows of this one tab.

Also have ready: the Sheet's **link** (from the browser address bar) and the **name of the tab** containing the data (visible at the bottom of the Sheet).

Step 1 — Get the project files onto the PC

Use **git clone** — not the green "Download ZIP" button. The `.git` folder that `git clone` creates is needed for the app to *work*, not just to keep history: the dashboard engine refuses to run any query without it. Verified under identical data and settings — with `.git` the database connection reports `connected`, without it `bruin query failed`. A folder taken from "Download ZIP" installs and starts normally, but leaves **every dashboard empty**, with no error message anywhere. The installer now stops at its first step if `.git` is missing.

Git is required for this step. If it isn't on the PC yet, install it from git-scm.com/download/win — the default options are fine. Then open a terminal (Start menu → type `cmd`) in the folder where the project should live, for example `C:\DevoTeam\`, and run:

```
git clone https://github.com/YusfAI/DevoTeam_Project.git
cd DevoTeam_Project
git checkout Version_2
```

Step 2 — Run the installer

Open the `DevoTeam_Project` folder that `git clone` just created, and **double-click `INSTALLER.bat`** at its root.

From here, it runs mostly by itself:

It handles automatically	You do this
Checks the folder is a real git clone	Nothing — but if it stops here, the project was not obtained with git clone. Redo Step 1.
Checks for Docker Desktop; installs it if missing	Nothing, unless Windows asks to restart (needed the first time virtualization is enabled) — restart if asked, then re-run <code>INSTALLER.bat</code>
Checks for Ollama (the local AI model), installs it if missing, starts its service if stopped, and downloads the model (~4.7 GB)	Nothing — just wait, this can take a few minutes

It handles automatically	You do this
Asks for the two values from <i>Before you start</i>	Type/paste the Sheet link or ID, then the tab name — one at a time. Pressing Enter keeps the value already there.
Builds the app and starts it	Nothing — several minutes the first time
Creates a desktop shortcut	Nothing
Runs a final check that the numbers shown are correct	Nothing — watch for "TOUT EST JUSTE" ("everything checks out") in the last block of text

If it stops partway (for example, asking for a Windows restart), that's normal — just **re-run `INSTALLER.bat`** after finishing that one step. It always picks up exactly where it left off, never repeating work already done.

Step 3 — Verify it worked

The installer runs this check itself at the end — nothing extra to do. It recalculates the dashboard numbers independently from the raw Sheet data and compares them to what the app actually shows.

- **"TOUT EST JUSTE"** (everything checks out) → installation is complete and correct. The browser opens automatically to `http://127.0.0.1:8000`.
- Anything else → don't present the app yet. Scroll up in the window to see which check failed, and see *Troubleshooting* below. It's safe to just close the window and re-run `INSTALLER.bat`.

Using it day to day

After this first install, starting the app is a single click:

- Double-click the **"DevoTeam Dashboard (Docker)"** shortcut created on the Desktop.
- The app opens in the browser at `http://127.0.0.1:8000` after a few seconds.
- It keeps running in the background even if that window is closed — no need to "stop" it between uses.

To fully shut it down (rarely needed): open a terminal in the project folder and run `docker compose down`.

To update to a newer version later: open a terminal in the project folder and run `git pull`, then `docker compose up -d --build` again. The `.env` file holding the settings is never overwritten by an update.

Troubleshooting

Symptom	Likely cause	Fix
"Access refused (403)" reading the Sheet	The Sheet isn't shared as "Anyone with the link" yet	Re-check the sharing setting from <i>Before you start</i>
Dashboards show empty / all zeros	Same as above — or the folder has no <code>.git</code> , because it came from "Download ZIP" instead of git clone	Re-run <code>INSTALLER.bat</code> ; it asks for the values again. If it stops on the <code>.git</code> check, redo Step 1 with git clone.
Dashboards work, but the figures look wrong — and nothing reports an error	The tab name typed during setup doesn't match a real tab in the Sheet	Google silently returns the FIRST tab instead of reporting the mistake. Re-run <code>INSTALLER.bat</code> and type the tab name exactly as it appears at the bottom of the Sheet.
Chat says "Ollama unreachable"	The local AI model isn't finished downloading, or isn't running	Wait a few minutes after install; re-run <code>INSTALLER.bat</code> if it persists
Windows asks to restart during install	Normal, first-time only (enables a required Windows feature)	Restart, then re-run <code>INSTALLER.bat</code> — nothing is lost
"Docker not started" / install seems stuck early on	Docker Desktop needs to be launched once by hand the very first time	Open "Docker Desktop" from the Start menu, accept its terms, then re-run <code>INSTALLER.bat</code>
Nothing else works	—	Take a screenshot of the error and send it over — the exact wording pinpoints the cause quickly
